

Rehearse — Interview Demonstration: Questions & Answers

Candidate: Kashish | Chitkara University (B.E. AI) | 5 Tailored Questions Based on Resume

Question 1: Telecom Customer Churn Prediction (AI/ML)

Question Asked: “Welcome Kashish. Could you introduce yourself and tell us about your Telecom Customer Churn Prediction project—specifically, what classification models you tested and which metrics you used to evaluate them?”

Key Competency: Machine Learning, Classification Models, Model Evaluation (Scikit-learn, Python)

- Situation:** I built a machine learning project to predict telecom customer churn to help businesses understand why customers leave and focus retention efforts on high-value users.
- Task:** I needed to prepare the customer dataset, train multiple classification models, and evaluate which model provided the best predictive performance.
- Action:** Using Python and Scikit-learn, I experimented with Logistic Regression and Random Forest classifiers. I conducted feature importance analysis to identify top churn factors like contract type and monthly charges. Because identifying at-risk customers early is critical, I prioritized Recall and ROC-AUC over simple accuracy.
- Result:** The Random Forest model achieved strong recall and provided actionable segmentation insights for customer retention campaigns.
-

Question 2: Data Preprocessing & Feature Engineering

Question Asked: “In your telecom churn analysis, how did you handle data preprocessing and feature engineering with Pandas and NumPy, especially for missing values and categorical data?”

Key Competency: Data Wrangling, Feature Scaling, Encoding & Data Hygiene (Pandas, NumPy)

- Situation:** The telecom customer dataset contained a mix of numerical metrics like total spend and categorical features like payment methods, with missing values in tenure records.
- Task:** I had to clean and preprocess the raw data so machine learning algorithms could process the features without bias or data leakage.
- Action:** I used Pandas to impute missing values using median values for skewed numerical columns. I applied One-Hot Encoding on nominal categorical variables such as contract type, and standardized continuous numerical features using StandardScaler from Scikit-learn.
- Result:** This data preprocessing pipeline ensured clean, normalized training data, improving model convergence and preventing overfitting.
-

Question 3: TOGETHERLY – LinkedIn Clone (Backend & Database)

Question Asked: “You built TOGETHERLY, a LinkedIn clone using Django and SQLite. How did you structure your models and implement user authentication, CRUD operations, and real-time messaging?”

Key Competency: Backend Architecture, Relational Schema, CRUD & Authentication (Django, SQLite)

- Situation:** I wanted to understand full-stack platform architecture by developing a professional networking platform with user profiles, posts, and peer-to-peer messaging.
- Task:** I needed to implement secure authentication, database relationships, and real-time interaction using Django and SQLite.
- Action:** I leveraged Django's built-in authentication system for secure passwords and sessions. I created relational models with foreign keys linking users to posts, comments, and connection requests. For messaging, I implemented conversation and message models with timestamped CRUD views.
- Result:** Togetherly allowed users to create accounts, publish posts with full CRUD operations, and send direct messages, giving me hands-on backend design experience.
-

Question 4: INNOFIND – Tech Resource Discovery Platform (Frontend)

Question Asked: “For INNOFIND, you created a tech resource discovery platform using HTML, CSS, and JavaScript. How did you implement local storage for data persistence across features like the to-do list and calendar?”

Key Competency: Frontend Engineering, DOM Manipulation & Client-Side Persistence (JavaScript)

Situation:	When learning tech concepts, students often lose track of helpful resources, tasks, and study schedules across different websites.
Task:	I built INNOFIND as a centralized discovery hub with an integrated to-do list, calendar, and themes, requiring client-side data persistence without a heavy backend.
Action:	I used the browser's localStorage API to store serialized JSON strings for user notes, tasks, and calendar events. When a user added or completed a task, the JavaScript state was updated and saved to localStorage. On page load, the app hydrated the UI from stored data.
Result:	Users could customize themes, organize their study calendar, and persist their daily tasks across browser sessions with zero server latency.

Question 5: Hackathons, Team Collaboration & Critical Thinking

Question Asked: “You've participated in hackathons like the Smart India Hackathon (SIH) and won second place in Intellex at Chitkara University. Tell me about a time in a team project or hackathon where you faced a tough technical roadblock and how you collaborated to solve it.”

Key Competency: Critical Thinking, Teamwork Under Pressure & Problem Solving

Situation:	During a hackathon, our team had only a few hours remaining before the final presentation when our frontend and backend data formats collided, breaking our live demo.
Task:	As a team, we needed to quickly diagnose the discrepancy and fix the API response structure without panic.
Action:	I called an immediate 10-minute huddle. Drawing on critical thinking techniques, we mapped the exact JSON schema required by our UI components. I took responsibility for updating our backend serializer to match the contract, while my teammate updated the frontend fetch handler.
Result:	We resolved the bug in thirty minutes, presented our working prototype on schedule to the judges, and placed successfully in the competition.
